**Abstract.** The protection of Critical Infrastructures (CIs) is, by definition, of high importance for the welfare of citizens, due to direct threats (dictated by the current international political situation) and also due to their dependencies at international and European levels. Today, Greece remains one of the few countries of the European Union, which has no comprehensive strategy to safeguard national CIs, nor any process of developing such an integrated plan, except for some initiatives taken from the General Secretariat of Digital Policy. This paper aims to contribute to: (i) The creation of an inventory of all stakeholders, (legislative, supervisory or regulatory) involved in CI protection in Greece, (ii) the identification of potential national CIs, as well as their interdependencies, (iii) the development of a structured identification based on impact assessment methodology for national CIs, that takes into account internationally applied CI assessment methodology.

# 1 Introduction

The protection of Critical Infrastructures (CIs) is, by definition, of high importance for the welfare of citizens of each country; especially nowadays, both because of direct threats (dictated by the current international political situation) and also due to emerging interactions or dependencies [13-15] developed between national CIs at international and European levels.

Today, Greece remains one of the few countries of the European Union, which, besides the formal transposition of the 114/2008/EC Directive into domestic legislation, has not implemented a comprehensive CI protection strategy, nor any process of developing such an integrated plan, except for some initiatives taken by the General Secretariat of Digital Policy. This paper presents some of the results which derived from the recent national project OLIKY<sup>1</sup> that aimed to provide a road-map towards the development of a holistic national CIP strategy for Greece. The basic goals of OLIKY included, among others:

1. The initial creation of an inventory and an initial ranking of candidate national CIs, along with their supervised entities, in order to identify the most critical services and their dependencies, to adequately protect and increase their resilience against known or unknown threats.

2. The assessment of critical services and interdependencies between candidate national CIs based on a methodology for the classification of national critical components.

Objectives of the OLIKY project did not include a comprehensive coverage and assessment of all national CIs, nor the proposal of a detailed security policy for each CI. This would not be feasible in the context of an independent study, since the complete recording and evaluation of all CIs nationwide requires an authorized body with the institutional and legal feasibility of collecting and processing classified information along with the cooperation of all national CI operators. However, an initial systematic identification and evaluation of Greek CIs may act as a catalyst for conducting such an in-depth analysis.

Contribution. The main contributions of this paper include:

1. The creation of an inventory of all stakeholders, (legislative, supervisory or regulatory) involved in the protection of the Greek CIs.

3. The identification of potential national CIs, as well as their interdependencies. In particular, an attempt was made to identify national CIs on the Energy, Transport and Information and Communication Technologies (ICT) sectors.

4. The development of a structured identification methodology for national CIs, taking into account internationally applied CI identification methodologies. A range of three evaluation levels (criticality) and specific evaluation criteria for the integration of critical components in criticality levels will also be developed and utilized, as part of the proposed methodology.

5. The pilot implementation of the proposed methodology to a list of candidate national CI fields in order to rank their criticality; namely on the Energy and ICT sectors.

### 2 A preliminary record of Greek Critical Infrastructures

The identification and evaluation of national CIs first requires the creation of an initial list of potential CIs, at sector and subsector levels. In this section, the services of three key critical sectors of the country are being mapped; namely those concerning the Energy, Transport and ICT sectors.

<sup>1</sup> The complete deliverables of the OLIKY project can be found (in Greek) at: http://www.dianeosis.org/2016/07/ideas\_infrastactures\_protection/

#### 2.1 Compilation of a National Protection Program for Critical Infrastructures

As part of a national CI protection program, each EU Member-State (MS) is required to: (i) record its National Critical Areas, (ii) record and evaluate the systems or parts thereof which may constitute a CI, and (iii) to record and evaluate (possible) interdependencies between the identified CIs. Also, each MS has to plan and/or update a Business Continuity Plan (BCP) and a Contingency Plan (CP) for the protection of its national CIs [1-6].

Since, in most cases, the owners and/or operators of CIs are private entities, any national CI identification process (along with all processes in the context of a national protection program) requires the exchange of information between stakeholders, in accordance with the principle of collaboration between stakeholders and the Public-Private Partnership (PPP) [12].

During the stage of critical area identification, each MS must establish an initial list of critical national sectors, i.e. sectors existing in the geographical limits of the country that include contingent CIs. Still, the process of selecting national critical sectors and sub-sectors is not obvious [2].

Towards creating a common framework program for the EPCIP (European Programme for Critical Infrastructure Protection) the establishment of a common list of critical sectors/subsectors is highly encouraged [1-6]. The concept of critical service is often used by implication instead of the term infrastructure, since it integrates the existence of a set of goods and processes that need protection and are examined in general and with detailed analysis. The list of CIs is presented in Table 1 and incorporates the concept of service per subsector.

Sector	Subsector	Service

Table 1. List of potential CIs, sectors and subsectors specifically for Greece

In order to identify candidate Greek CIs, the ENISA List of Critical Sectors and Related Critical Services [7] was used to create an overview of the Critical Sectors as reported in Table 1, where specific areas were selected as being more significant for the country. Potential critical services which were irrelevant to Greek Activities (e.g. Space sector) were removed from the list due to non-conformity, while others have been added due to their potentially high impact on Greece's GDP, like Tourism and associated services. Based on the collection of public information and scientific expertise of the panel members, the following critical areas were selected for our study: (a) Energy (b) Information and Communications Technologies (ICT) and (c) Transportation.

Results from identifying interdependencies and main stakeholders for these three fundamental CI sectors are presented in Table 2, 3 and 4 respectively. These tables contain critical domains, sub domains for each critical service, the key subsystems that are necessary for providing each service, the essential interdependencies with other (sub) sectors, as well as an indicative inventory of the providers of each service involved in the country.

#### **Energy sector**

In Greece, multiple providers support various subsectors of the Energy sector. In some subsectors, only one provider (or a very small number of them) has a dominant position, making him the obvious choice for a CI at the Energy sector. Still, some changes have occurred in the Energy market of other subsectors over the last years; usually because of Greece's need to comply with the relevant European Directives, but also due to the economic situation of the country.

Critical	Critical	Interdepe	ndencies	Main Stakeholders
Subsector	Service	Depends upon	Affects	Main Stakeholders
	AC/DC	Mining of Lignite General Transfer	All sectors	Public Power Corporation (DEI) Alternative Electric

Table 2. Summary of the Energy Sector in Greece

# ICT sector

The Information and Telecommunication Technologies (ICT sector) is a sector of high criticality since it provides information assets and services to almost all other critical services in the country. Of all the ICT subsectors, it appears that the Telecommunication subsector is the most important in Greece. Hardcore centralization of services is observed at the Greek ICT sector, although for some services there seems to be a more balanced distribution of providers. For this reason several providers have been identified as candidate CIs for this sector, although the "weight" of each candidate may significantly vary.

Critical Subsector	Critical Service	Interdependen	icies	Main Stakeholders
Critical Subsector	Cilical Service	Depends upon	Affects	Main Stakenoluers

Table 3. Summary of the ICT Sector in Greece

# **Transportation Sector**

The transport sector provides services to multiple other sectors and supports numerous economic activities such as trading, tourism, industry, rural development and the exploitation of natural resources of Greece. The sector is subdivided into Road, Sea, Air and Rail transport along with postal services.

Critical	Critical	ort along with postal servi Interdependenci

# **3** Method for determining & evaluating national CIs

This section describes a methodology for identifying and evaluating national CIs, structured as a sequence of steps. Each step provides a brief description, the data (or parameters) input necessary for the execution, implementation actions needed and expected results. The development of the methodology took into consideration previous work from other EU members [7-12, 16-20, 26], since following a best practice and creating a common baseline throughout the EU is of outmost importance.

Categories of criteria for the integration of candidate CIs were defined inside the methodology. These include direct assessment criteria, time-based criteria and indirect criteria used to evaluate the "importance" of the CIs. Direct evaluation criteria are based on the assessment of potential impact (impact-based classification) that are expected to manifest after an attack on relevant infrastructures. Time-based criteria such as estimated recovery time, and estimated impact evolution over time are used for prioritizing CIs within each risk level. Indirect criteria consider, amongst others, second order dependencies, which may eventually upgrade a candidate CI to a higher criticality level, e.g., when other critical elements depend on it. Indeed, the analysis of interdependencies between CIs can identify CIs that might have been underestimated during previous analysis [13-15, 21-25].

For each critical service sectorial and horizontal criteria are utilized for the identification of its most important subsystems. The methodology does not take into account threats (threats or scenarios), nor does it assess them according to their likelihood. A schematic overview of the described Methodology is presented in Figure 1.

# STEP 1: Initial list of critical sectors and subsectors.

*Short description.* In the first step an initial list of potential national critical sectors and subsectors per sector is catalogued. Sectors and subsectors from the list of services offered in Table 1 are used as input.

*Implementation.* Cataloguing of the initial sectors/-subsectors list is performed by a central authority. Typically, this can be coordinated by the respective competent body for the protection of national CIs.

*Results.* The initial list of critical sectors/sub-sectors will be given as input to Step 2 and Step 3.

#### STEP 2: Identify potential critical services per sector/subsector.

*Short description.* For each critical area, potential critical services are identified. The list compiled from Step 1 can be considered as initial parameter in the process of identifying potential critical services per sector/sub-sector, along with good-practices from EU members [9-12] which are mature enough when it comes to implementing strategies for the protection of national CIs.

*Implementation.* There are two alternative approaches that can be followed to identify possible national critical services sector/subsector [7]:

Administrative Approach. A list of potential national critical sector services is compiled at a central, administrative level, in cooperation with a competent Authority. According to Operator-based approach, a Critical Operator list is compiled (according to relevant legal frameworks). Operators will be responsible to identify critical services that are involved in.

*Results.* The list of critical services sector/subsector will be given as input to Step 3 for the risk assessment of possible critical services per sub-sector.

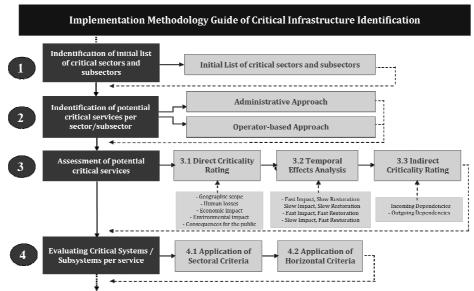

Figure 1. Schematic overview of Methodology Steps

#### **STEP 3:** Assessment of potential critical services.

*Short description.* Possible critical elements from previous steps (sub-sector and/or services by sub-sector) are assessed and prioritized using specific criteria. Initial parameters that can be considered for the evaluation of potential critical subsectors/services are:

- The initial list of possible critical sectors/subsectors from Step 1.
- The initial list of potential critical services from Step 2 (this list may include the list from Step 1).
- The non-binding guidelines of the European Council [5] on the implementation of the horizontal criteria during the evaluation of CIs.
- Good practices from EU members [12].

*Implementation.* Depending on the approach taken during Step 2 (Administrative approach or Operator-based approach), the following checks are applied, either at central level or in collaboration with Critical Administrators:

*Step 3.1. Direct criticality rating.* All potential critical services are assessed, based on the immediate consequences that would result from their breach or failure. This is achieved by applying selected horizontal criteria, from the following list [5-6]:

- Geographic scope: The scope of the area to be affected by an event.
- Human losses: The number of victims and/or injured people.
- Economic impact: The impact in a macro and/or macro-social level.
- Environmental impact: Long-term environmental effects.
- Consequences for the public: Impact of events affecting the people, which does not directly relate to any of the previous criteria.

*Step 3.2. Temporal effects analysis.* The following are evaluated for each critical service: (a) the time required for the manifestation of maximum impact and (b) the time required to fully restore a service after a possible attack manifestation. Time analysis is used for the classification of critical services within each level of criticality. Temporal analysis is used for prioritizing services within the same criticality level. Specifically, depending on the scores for (a) and (b) each critical element is assigned to a specific category (Step 3.3).

*Step 3.3. Indirect criticality rating.* Any possible critical service is also analyzed based on the indirect effects that can cause during a failure scenario. Indirect effects depend on two factors:

- Dependencies of the service in question with other critical services. Whether and how much other critical elements may depend on this particular service.
- Evaluation of indirect criticality is performed by utilizing one or more horizontal criteria, from Step 3.1.

*Results*. The list of prioritized sub-sectors and services per sub-sector, as well as a table of interdependencies between sub-sectors/services will be provided as input to Step 4, to assess the criticality of (sub) systems per critical service. This step determines a list of possible European critical sectors/subsectors or services. For each horizontal criterion to be applied, criticality levels are described using a quality scale (e.g. Low, Medium, High). For each level, a minimum quantitative impact threshold is set.

#### STEP 4: Evaluating Critical (sub) systems per service.

*Short description.* For each critical service, a list of involved owners-managers is compiled, from which (or in collaboration with whom) a second list of the most critical subsystems that support this service is compiled.

*Implementation.* According to the approach proposed by the EPCIP framework [5-6], certain criteria must be applied at each sub-sector for the characterization of a subsystem as a possible CI inside a service (Step 4.1). This is to check whether a subsystem meets at least one horizontal criticality criterion (Step 4.2).

*Results.* This step provides a list of the most critical subsystems per service. This will be the actual list of national CIs, according to the 114/2008/EC Directive. As part of a National CI Protection Program, CI owners-operators in collaboration with a qualified national body must identify the most important assets per critical subsystem and develop Operation Security Plans (OSP) and Contingency Plans (CP) to protect the CIs (Annex II - 114/ 2008/EC Directive).

*Step 4.1: Application of Sectoral Criteria:* Sectoral criteria are technical or operational criteria used to identify potential critical subsystems. These criteria do not report, although hint, potential repercussions (e.g. obstruction or shutdown of a subsystem). Instead, they only refer to certain inherent characteristics. In particular, the sectoral criteria may refer to [5-6]:

- Technical properties. For example, quantifiable characteristics, such as dimensions, capacities, distances, speed, data volume, etc.
- Non-technical properties. For example, identifiable features such as recovery time, recovery costs etc.

To identify a subsystem as potentially critical, it should exceed a predetermined threshold (threshold) concerning the values of some sectoral criteria.

*Step 4.2: Application of Horizontal Criteria*: For each subsystem that provides essential services, we assess the severity that its loss or dysfunction would have on society. A subsystem is critical when it meets at least one of the horizontal criticality criteria, concerning the direct (Step 3.1) or indirect criticality (Step 3.2).

Also, criticality evaluation takes into account parameters such as the availability of alternatives, the turning-point for "painful" consequences, as well as the time needed for recovery.

# STEP 5: Periodic re-assessment of CIs.

*Short description.* All critical and relevant factors concerning the criticality of a CI and relevant services should be reassessed after some time by applying all steps of the methodology at regular intervals.

*Input data*. All results of the previous evaluation of critical components (sectors, subsectors, services, systems).

*Implementation.* The reassessment may be general (step 1, taking into account the previous critical services list), or may refer to a particular sector/subsector (step 3) or service (step 4). The reassessment scope is determined by a qualified body in collaboration with stakeholders. The need for reassessment should be determined on a midterm basis; the period must be fixed in advance, regardless of whether changes in the collected data occur or not.

*Results.* The amended list of critical elements and CIs or the update of the previous assessment of critical components (domains, subdomains, services and systems.

#### 3.1 Applying evaluation criteria on candidate national CIs

After establishing all parameters for evaluating potential CIs, the description of the national CI assessment methodology is complete and will now be applied to the Greek Energy and ICT sectors.

It should be noted here that during the implementation of the horizontal evaluation criteria, the estimated impact always refers to the worst-case scenario. Therefore, when analyzing potential impact values listed in the tables below, the value attributed to each impact corresponds to the most negative potential effect that is likely to occur.

Also when we applied the criteria, there happened to be some cases where the assessment could not get unique value assignments, thus values were assigned on the 1-2 impact scale. When a qualified national body implements a full version of the above methodology, every service criterion should be assigned only one scale value.

### **Evaluation of the Energy Sector.**

The Energy Sector includes the following sub-sectors: Electricity, Oil and Natural Gas. Table 3, 4 and 5 summarize the evaluation of each sub-sector and key dependencies recorded, incoming and outgoing, by sub-sector.

Based on the application of the evaluation criteria and taking into account the record from providers/-operators per service, our evaluation provided the following:

- In the Electricity sub-sector all services are assessed as high critical, both for direct and indirect dependencies. To an extent, they also depend on one provider/IM (PPC).
- Concerning the temporal analysis of impact, the Production and Distribution services have higher priority than the electricity market service, as far as recovery time is concerned.
- At the subsystems level, all subsystems used to support this sector's services must be tested using corresponding sectoral criteria.

# **Evaluation of the ICT sector.**

The ICT sector includes the Telecommunications and Information Technologies subsectors. Tables 6 presents the evaluation of these subsectors.

Based on the application of the evaluation criteria and taking into account the record from providers/operators per service, our evaluation provided the following:

- The Communications sub-sector has increased impact in Greece. All services showed that they are of high criticality, both in direct and in indirect evaluations of dependencies. The Communications sub-sector services depend to a large extent, from a single provider (OTE).
- Concerning the temporal analysis of impact, it was shown that both the voice/data communication services and the provision of Internet services present fast impact effects but rapid recovery times, thus fall within the same priority level.
